## mathematical content

Given a dataset  $\mathcal{D} = \{(\mathbf{x}_i, \mathbf{y}_i)\}_{i=1}^N$ , we aim to:

$$\min_{\theta} \frac{1}{N} \sum_{i=1}^N \mathcal{L}(f_{\theta}(\mathbf{x}_i), \mathbf{y}_i)$$

where:

- ▶  $f_{\theta}$  is the model with parameters  $\theta$
- ▶  $\mathcal{L}$  is the loss function

# code example

```
import torch
import torch.nn as nn

class Model(nn.Module):
    def __init__(self, input_dim, output_dim):
        super().__init__()
        self.linear = nn.Linear(input_dim, output_dim)

    def forward(self, x):
        return self.linear(x)
```
